

# Topics

---

## Hierarchical modeling

- Examine the limitations of linear modeling
  - Symbols and instances

## **Model Complicated Objects**

---

So far, we have discussed modeling simple geometrical objects.

How can we generate a complicated object, e.g., a robot, which is made up from several parts?

Construct complex objects from a collection of basic objects.

# Instance Transformation

Start with a prototype object (a *symbol*), e.g.,

- Geometric objects
- Fonts

Each appearance of the object in the model is an *instance*

- A instance transformation from model frame to world frame by scaling, rotation, and translation

$$\mathbf{M} = \mathbf{TRS}$$

# Instance Transformation

A model view matrix consists of

- instance transformation and
- a transformation from the world frame to the eye frame

```
mat4 instance; mat4 model_view;
```

```
instance = Translate(dx, dy, dz)*RotateZ(rz)*RotateY(ry)*RotateX(rx)*Scale(sx, sy, sz);
```

```
model_view = model_view*instance;
```

# Symbol-Instance Table

---

Can store a model by assigning a number to each symbol and storing the parameters for the instance transformation

What's the problem with the table?

A flat structure - each symbol is processed independently.

Symbol	Scale	Rotate	Translate
1	$s_{x'}, s_{y'}, s_z$	$\theta_{x'}, \theta_{y'}, \theta_z$	$d_{x'}, d_{y'}, d_z$

## Relationships in Car Model

---

Symbol-instance table does not show relationships between parts of model

Consider model of car

- Chassis + 4 identical wheels
- Two symbols

Rate of forward motion determined by rotational speed of wheels

# Structure Through Function Calls

---

```
car (speed)
{
    chassis ()
    wheel (right_front) ;
    wheel (left_front) ;
    wheel (right_rear) ;
    wheel (left_rear) ;
}
```

Fails to show relationships well

**Represent the relationships among different parts  
using a graph**

# Graphs

---

Set of **nodes** and **edges** (*links*)

Edge connects a pair of nodes

- Directed or undirected

*Cycle*: directed path that is a loop

# Graphs: Tree

---

**Tree is a directed acyclic graph (DAG)**

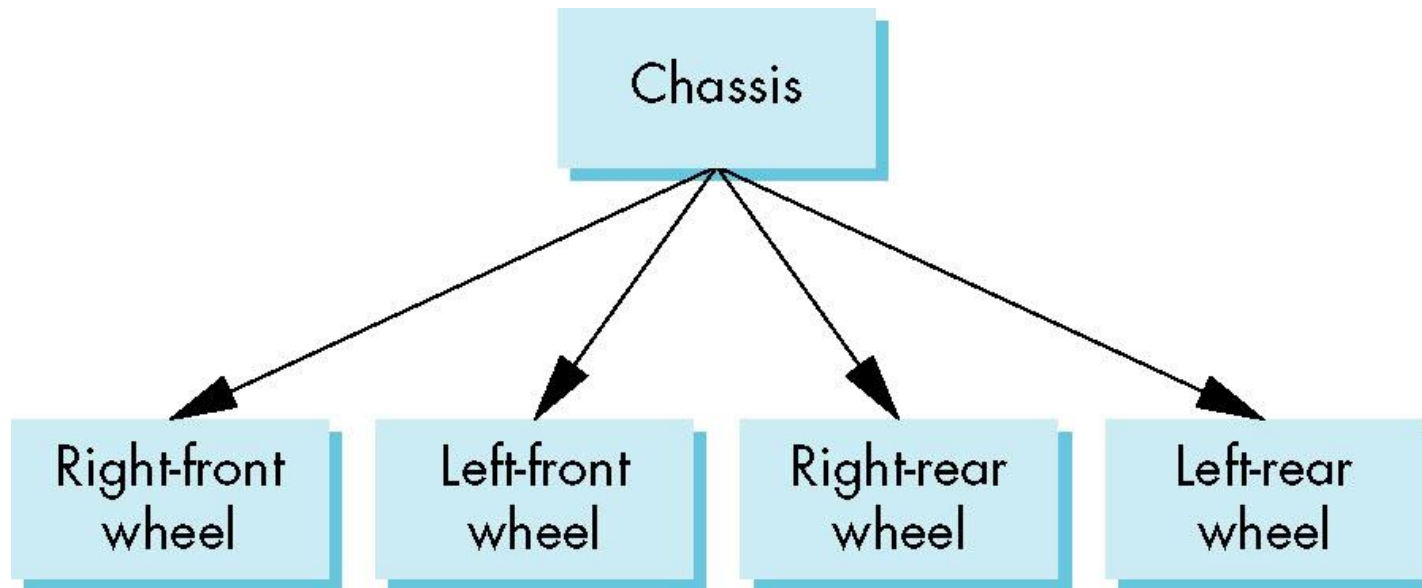

**A directed graph in which each node (except the root) has exactly one parent node**

- No loops
- May have multiple children
- Leaf or terminal node: no children

# Tree Model of Car

---

# DAG Model

---

If we use the fact that all the wheels are identical, we get a *directed acyclic graph*

- Not much different than dealing with a tree

# Modeling with Trees

---

Must decide what information to place in nodes and what to put in edges

## Nodes

- What to draw
- Pointers to children

## Edges

- May have information on incremental changes to transformation matrices (can also store in nodes)

# A Robot Arm

A robot arm consists of two parallelepipeds and a cylinder

robot arm

parts in their own  
coordinate systems

# Articulated Models

---

Robot arm is an example of an *articulated model*

- Parts connected at joints
- Three degrees of freedom described by
  - joint angles measured in its local frame
  - Angle between the base and the ground

# Relationships in Robot Arm

---

## Base rotates independently

- Single angle determines position

## Lower arm attached to base

- Its position depends on rotation of base
- Must also translate relative to base and rotate about connecting joint

## Upper arm attached to lower arm

- Its position depends on both base and lower arm
- Must translate relative to lower arm and rotate about joint connecting to lower arm

## Required Matrices

---

Base:

- Rotation of base:  $R_b$ 
  - Apply  $\mathbf{M} = \mathbf{R}_b$  to base

Lower arm:

- Translate lower arm relative to base:  $T_{lu}$
- Rotate lower arm around joint:  $R_{lu}$ 
  - Apply  $\mathbf{M} = \mathbf{R}_b \mathbf{T}_{lu} \mathbf{R}_{lu}$  to lower arm

Upper arm:

- Translate upper arm relative to lower arm:  $T_{uu}$
- Rotate upper arm around joint:  $R_{uu}$ 
  - Apply  $\mathbf{M} = \mathbf{R}_b \mathbf{T}_{lu} \mathbf{R}_{lu} \mathbf{T}_{uu} \mathbf{R}_{uu}$  to upper arm

# OpenGL Code for Robot

```
mat4 ctm;  
robot_arm()  
{  
    ctm = RotateY(theta);  
    base();  
    ctm *= Translate(0.0, h1, 0.0);  
    ctm *= RotateZ(phi);  
    lower_arm();  
    ctm *= Translate(0.0, h2, 0.0);  
    ctm *= RotateZ(psi);  
    upper_arm();  
}
```

# OpenGL Code for Robot Base

---

```
void base()
{
    mat4 instance = ( Translate( 0.0, 0.5 * BASE_HEIGHT,
0.0 ) *Scale( BASE_WIDTH, BASE_HEIGHT,BASE_WIDTH ) );

    glUniformMatrix4fv( ModelView, 1, GL_TRUE,
model_view * instance );

    glDrawArrays( GL_TRIANGLES, 0, NumVertices );
}
```

## OpenGL Code for Robot

---

The lower arm and the upper arm are modeled similar to the base.

All the three parts are modeled based on cubes – the same symbol.

Only one set of vertices are needed to send to the buffer!

# Tree Model of Robot

---

Note code shows relationships between parts of model

- Can change “look” of parts easily without altering relationships

Simple example of tree model

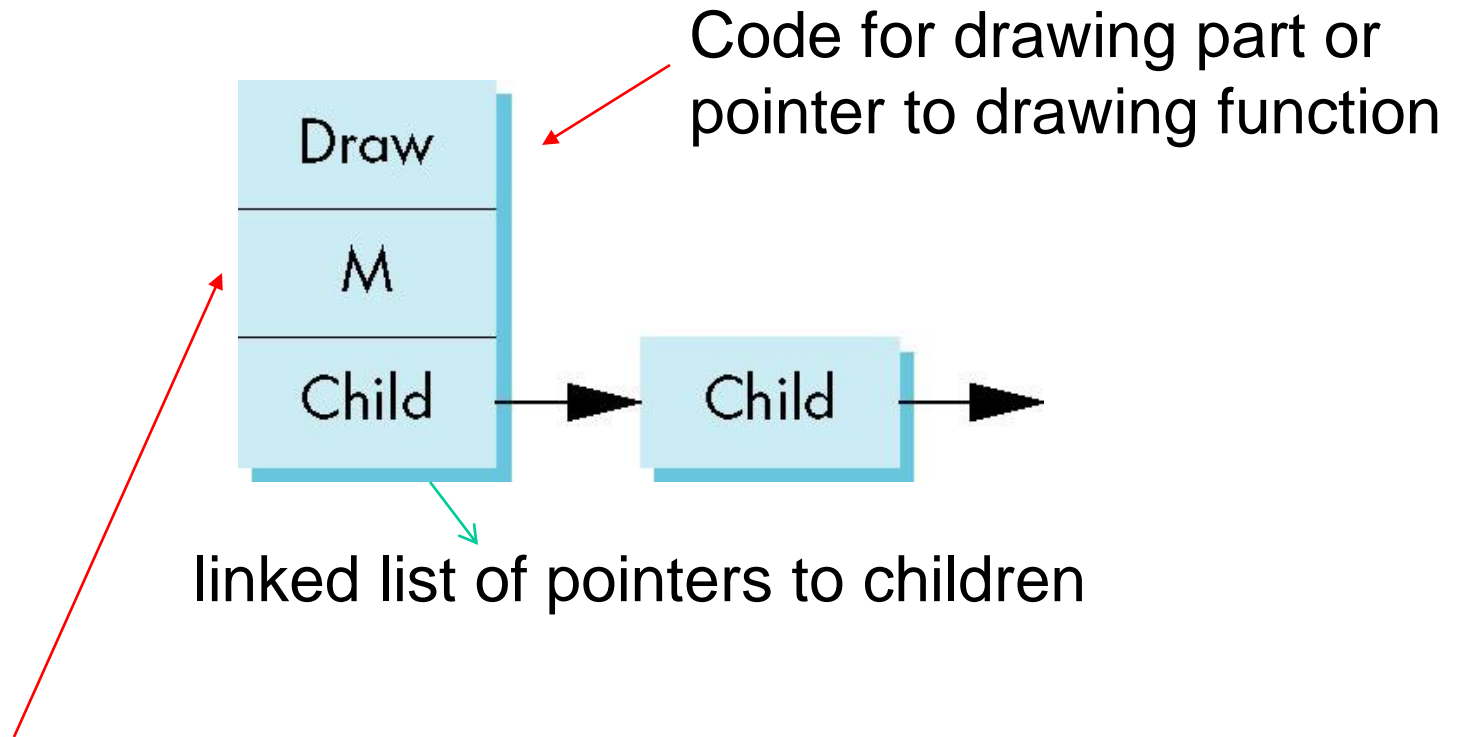

Want a general node structure for nodes

-- storing all information in nodes

# Possible Node Structure

---

A matrix relating node to parent

# Generalizations

---

## Need to deal with multiple children

- How do we represent a more general tree?
- How do we traverse such a data structure?

## Animation

- How to use dynamically?
- Can we create and delete nodes during execution?

# Humanoid Figure

---

# Building the Model

---

Can build a simple implementation using quadrics:

- ellipsoids and cylinders

Access parts through functions drawing individual parts in their own frames

- `torso()`
- `left_upper_arm()`

Matrices describe position of node with respect to its parent

- $\mathbf{M}_{lla}$  positions left lower arm with respect to left upper arm

# Tree with Matrices
